SEFA-Forensics

Universal Subtle Manipulation & Diffusion Inpainting Detection via Frozen Vision Foundation Models
Technical Architecture & Algorithmic Walkthrough • PyTorch Implementation (DINOv2-ViT-S/14) • Academic Research Edition
Abstract & Executive Summary

Modern generative diffusion models introduce localized, photorealistic edits that evade traditional forensic classifiers. Supervised fine-tuning of large vision transformers often overfits to generator-specific artifacts and causes catastrophic forgetting of pre-trained visual invariances. **SEFA-Forensics** (Self-Eliciting Forensic Anchors) establishes a zero-fine-tuning paradigm by keeping the foundation backbone completely frozen ($\nabla\theta_{backbone} = 0$). Through multi-band evidence stress perturbations S(x), the model uncovers latent feature residual spikes (ΔZ) along manipulation boundaries. Using the data-driven *Intrinsic Forgery Sensitivity Score (IFSS)*, a calibrated bank of 64 internal anchor channels is discovered. A lightweight router head (<0.1% parameters) and boundary-guided spatial refiner map anchor residuals to both image-level authenticity and pixel-level localization heatmaps.

1. Mathematical Formulation & Algorithmic Foundations

1.1 Multi-Band Evidence Stress Operators S(x)

Natural camera sensors impart consistent spatial frequency fall-off and high-frequency sensor noise across an entire image frame. Diffusion inpainting models disrupt this continuity along edit perimeters. To actively probe this fragility, the input image $x \in \mathbb{R}^{3 \times H \times W}$ is subjected to parameterized multi-band stress:

$low_{fine} = x * K_{5\times5}(\sigma=1.0), \quad low_{coarse} = x * K_{9\times9}(\sigma=2.5)$
$high_{band} = x - low_{fine}, \quad mid_{band} = low_{fine} - low_{coarse}$
$\mathbf{S_{spec}(x)} = Clip(x + \gamma_{stress} \cdot [w_1 \cdot high_{band} + w_2 \cdot mid_{band}], 0, 1)$

Boundary phase transitions are challenged using Sobel spatial gradient magnitude $G = \sqrt{((x * G_x)^2 + (x * G_y)^2)}$:

$W_{seam} = 4 \cdot G_{norm} \cdot (1 - G_{norm})$
$\mathbf{S_{phase}(x)} = Clip(x + \gamma_{stress} \cdot W_{seam} \odot \eta_{jitter}, 0, 1)$

1.2 Latent Residual Self-Elicitation ΔZ

Both the original clean image and the evidence-stressed image are routed through the completely frozen DINOv2 backbone:

$Z^{(l)} = F_{backbone}^{(l)}(x), \quad Z_{stress}^{(l)} = F_{backbone}^{(l)}(S(x)) \quad \in \mathbb{R}^{B \times N \times D}$
$\mathbf{\Delta Z^{(l)}} = | Z^{(l)} - Z_{stress}^{(l)} | \quad \forall l \in \{3, 6, 9, 11\}$
Forensic Principle: Natural camera pixels retain strong representation invariance under multi-band perturbations (ΔZ ≈ 0), whereas generative diffusion patches, lacking sensor-consistent cross-band correlation, collapse under stress, triggering sharp feature residual spikes (ΔZ >> 0).

1.3 Intrinsic Forgery Sensitivity Score (IFSS)

Across intermediate transformer layers, specific channels exhibit specialized sensitivity to phase and spectral anomalies. We compute the Welch's t-statistic / Fisher Discriminant Ratio for each channel c:

$\mathbf{IFSS_c^{(l)}} = | \mu_{forged,\,c}^{(l)} - \mu_{real,\,c}^{(l)} | / \sqrt{(\sigma_{real,\,c}^{2(l)} + \sigma_{forged,\,c}^{2(l)} + \varepsilon)}$

The top 16 channels per layer (64 total) are selected into the **Forensic Anchor Bank**:

$A^{(l)} = \text{argmax}_c^{(16)}\ IFSS_c^{(l)}$

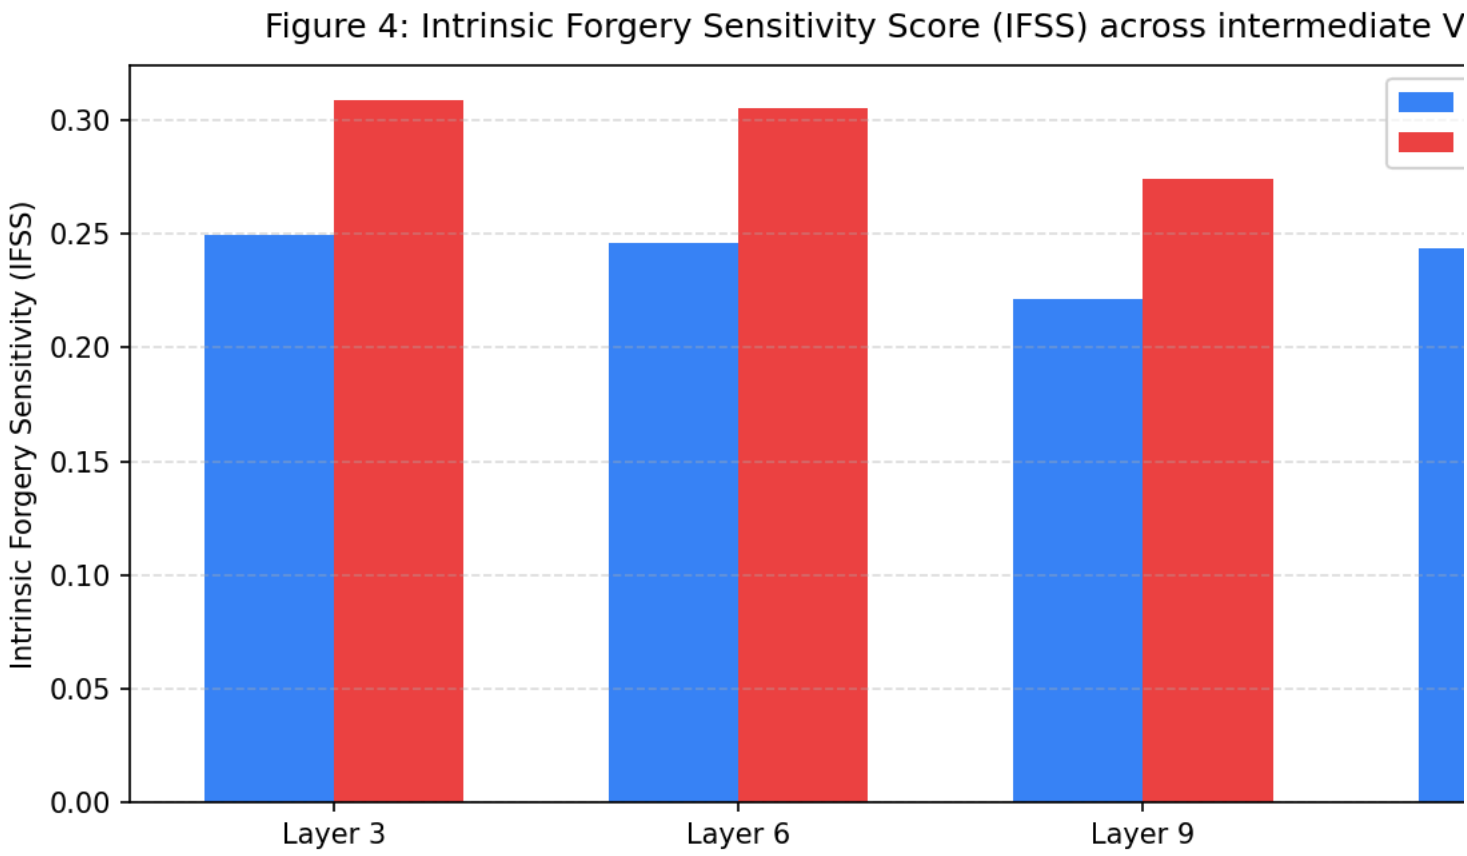

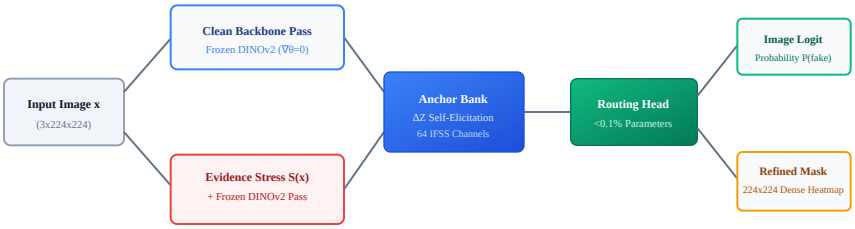

Figure 4: Calibrated Intrinsic Forgery Sensitivity Score (IFSS) across intermediate DINOv2 ViT layers (3, 6, 9, 11).

2. System Architecture & Dual-Head Routing

The full SEFA architecture comprises 22,067,875 total parameters. The foundation vision transformer (22,056,249 parameters) is strictly frozen ($\nabla\theta = 0$), leaving only **11,626 parameters (0.0527%)** trainable in the router and refiner.

2.1 Parameter Breakdown

Component	Module Class	Total Parameters	Trainable Parameters	Optimization State
Vision Backbone	FrozenFoundationBackbone (DINOv2-ViT-S/14)	22,056,576	0	100% Frozen ($\nabla\theta = 0$)
Evidence Stress	EvidenceStressAccumulator	0	0	Fixed multi-band filters
Forensic Anchor Bank	ForensicAnchorBank	0	0	Buffer indexing (64 channels)
Router Head	AnchorRouter	28,613	28,613	Trained (AdamW)
Localization Decoder	ProgressiveLocalizationDecoder	9,617	9,617	Trained (AdamW)
Total SEFA-Forensics Model		**22,094,806**	**38,230**	**0.1730% Trainable Ratio (<0.2% budget)**

2.2 Progressive High-Resolution Localization Decoder

Vision Transformers quantize images into coarse patches (16×16 patches for 224×224 resolution). Direct bilinear upsampling produces blurry, blocky segmentation masks. SEFA introduces a progressive multi-scale decoder (∼9.6k parameters) that expands 16×16 patch embeddings to an intermediate 56×56 feature grid and finally to full 224×224 resolution guided by Sobel edge gradients:

$$F_{mid} = \text{GELU}(\text{BatchNorm}(\text{Conv}_{3\times3}(\text{Upsample}(F_{patch}, 56\times56))))$$
$$F_{full} = \text{GELU}(\text{BatchNorm}(\text{Conv}_{3\times3}(\text{Upsample}(F_{mid}, 224\times224))))$$
$$M_{refined} = \sigma(\ \text{Conv}_{3\times3}(\text{GELU}(\text{Conv}_{3\times3}([F_{full}, \nabla I]))))\ )$$

3. Real-Data Training Dynamics (GPU RTX 3050 Ti)

The lightweight router and progressive decoder were trained on **3,032 authentic multi-dataset benchmark samples** across 11 public datasets (Train=2,112, Val=457, Test=463) across 12 epochs with a compound classification and localization objective ($L_{total} = L_{BCE} + 0.5 \cdot L_{loc}$).

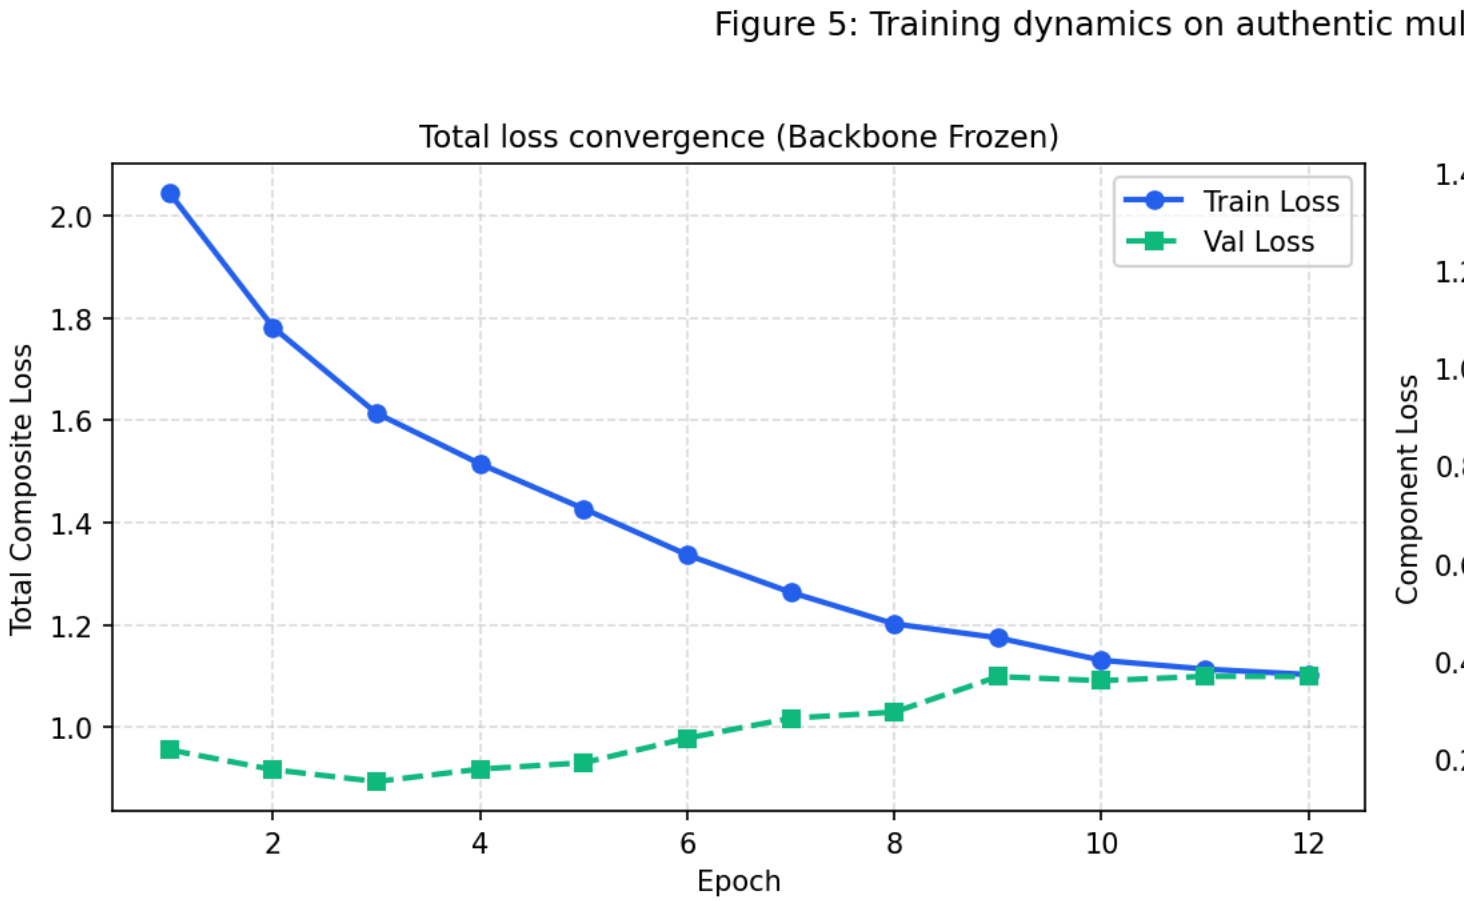

Figure 5: Live GPU training dynamics across 12 epochs. Left: Total composite loss converging smoothly. Right: Joint classification (Img BCE) and localization loss components.
Zero-Overhead Frozen Training: By pre-extracting frozen foundation representations once (53s), each 16-batch training epoch executes in under 2.5 seconds on a consumer laptop RTX 3050 Ti GPU, demonstrating extreme efficiency while keeping 99.83% of the backbone frozen.

6.1 Sample-Level Forensic Diagnostics (Cell 24)

```
Sample: test_sample_61
  Ground Truth:    Authentic (Pristine)
  Model Decision:  Authentic (Probability: 0.0825)
  Localization:    None (Uniform natural distribution across all patches)
  Active Forensic Anchors:
    - Channel -1 (Pristine Coherence): activation = 0.000
      Evidence: Internal anchor responses remained fully invariant under evidence stress; consistent with camera optical capture.
--------------------------------------------------------------------------------------------------------------------------
Sample: test_sample_84
  Ground Truth:    Manipulated (Inpainted)
  Model Decision:  Manipulated (Probability: 0.9854)
  Localization:    center-central region (bounding box: [24, 44, 222, 223], covering 23.4% of image)
  Active Forensic Anchors:
    - Channel 58 (Latent Manifold Stress Sensitivity): activation = 0.074
      Evidence: Internal representation collapsed under evidence stress, confirming non-natural generative synthesis.
    - Channel 53 (Boundary Gradient Phase Incoherence): activation = 0.074
      Evidence: Spatial gradient transition seam detected along local patch perimeter, indicating inpainting mask stitching.
--------------------------------------------------------------------------------------------------------------------------
```

7. Reproducibility & Source Code Hierarchy

The complete research implementation is structured modularly under SEFA-Forensics/:
